About IJSTER

International Journal of Science and Technology Education Research (IJSTER) is a peer reviewed open access journal. The journal is published quarterly and covers all areas of the subject.

Open Access Policy

Open Access is a publication model that enables the dissemination of research articles to the global community without restriction through the internet. All articles published under open access can be accessed by anyone with internet connection.

The International Journal of Science and Technology Education Research is an Open Access journal. Abstracts and full texts of all articles published in this journal are freely accessible to everyone immediately after publication without any form of restriction.

Article License

All articles published by International Journal of Science and Technology Education Research are licensed under the [Creative Commons Attribution 4.0 International License](#). This permits anyone to copy, redistribute, remix, transmit and adapt the work provided the original work and source is appropriately cited. Citation should include the article DOI. The article license is displayed on the abstract page the following statement:

This article is published under the terms of the [Creative Commons Attribution License 4.0](#)

Please refer to <https://creativecommons.org/licenses/by/4.0/legalcode> for details about [Creative Commons Attribution License 4.0](#)

Article Copyright

When an article is published by in the International Journal of Science and Technology Education Research, the author(s) of the article retain the copyright of article. Author(s) may republish the article as part of a book or other materials. When reusing a published article, author(s) should;

Cite the original source of the publication when reusing the article. i.e. cite that the article was originally published in the International Journal of Science and Technology Education Research. Include the article DOI
Accept that the article remains published by the International Journal of Science and Technology

Education Research (except in occasion of a retraction of the article)
The article is licensed under the Creative Commons Attribution 4.0 International License.

A copyright statement is stated in the abstract page of each article. The following statement is an example of a copyright statement on an abstract page.

Copyright ©2016 Author(s) retains the copyright of this article.

Self-Archiving Policy

The International Journal of Science and Technology Education Research is a RoMEO green journal. This permits authors to archive any version of their article they find most suitable, including the published version on their institutional repository and any other suitable website.

Please see <http://www.sherpa.ac.uk/romeo/search.php?issn=1684-5315>

Digital Archiving Policy

The International Journal of Science and Technology Education Research is committed to the long-term preservation of its content. All articles published by the journal are preserved by Portico. In addition, the journal encourages authors to archive the published version of their articles on their institutional repositories and as well as other appropriate websites.

<https://www.portico.org/publishers/ajournals/>

Metadata Harvesting

The International Journal of Science and Technology Education Research encourages metadata harvesting of all its content. The journal fully supports and implement the OAI version 2.0, which comes in a standard XML format. See Harvesting Parameter

Memberships and Standards

Academic Journals strongly supports the Open Access initiative. Abstracts and full texts of all articles published by Academic Journals are freely accessible to everyone immediately after publication.

All articles published by Academic Journals are licensed under the [Creative Commons Attribution 4.0 International License \(CC BY 4.0\)](#). This permits anyone to copy, redistribute, remix, transmit and adapt the work provided the original work and source is appropriately cited.

[Crossref](#) is an association of scholarly publishers that developed Digital Object Identification (DOI) system for the unique identification published materials. Academic Journals is a member of Crossref and uses the DOI system. All articles published by Academic Journals are issued DOI.

[Similarity Check](#) powered by iThenticate is an initiative started by CrossRef to help its members actively engage in efforts to prevent scholarly and professional plagiarism. Academic Journals is a member of Similarity Check.

[CrossRef Cited-by](#) Linking (formerly Forward Linking) is a service that allows you to discover how your publications are being cited and to incorporate that information into your online publication platform. Academic Journals is a member of [CrossRef Cited-by](#).

Academic Journals is a member of the [International Digital Publishing Forum \(IDPF\)](#). The IDPF is the global trade and standards organization dedicated to the development and promotion of electronic publishing and content consumption.

Laboratory report on quantification of anacardic acids from pistachio hulls

Martin Aborah

Department of Chemistry and Advanced Chemical Methodologies, School of Science and Technology, University of Camerino, Italy.

Received 30 January, 2022; Accepted 31 March, 2022

Pistachio hull contains anacardic acids. It is a salicylic acid with a side chain either saturated or unsaturated. This work focused on the efficient extraction of anacardic acids using solvent. Six aliquots were weighed and extracted with hexane, ethyl acetate, and mixture of H₂O/MeOH/HCl. Hexane was the most efficient solvent due to its ability to dissolve the anacardic acids. Only one anacardic acid standard was used to quantify all of them since the side chain does not affect the wavelength to a greater extent. HPLC-DAD was used for quantification purposes and HPLC-MS and retention time were used for qualitative analysis.

Key words: Anacardic acid, maceration, salicylic acid, pistachio hulls.

INTRODUCTION

Pistachio is a member of the cashew family found mostly in Central Asia and Middle East. The tree produces seeds that are consumed as food (<https://en.wikipedia.org/wiki/Pistachio>). Pistachio hull (external soft shell of pistachio) is the major part of pistachio by-product that has a high content of bio-active compounds (such as polyphenols, tocopherols, dietary fibers, essential oils, and unsaturated fatty acid) with antioxidant properties and health-promoting effects. Pistachio hulls were previously shown to contain a large diversity of phenolic compounds, including gallotannins, flavonoids, and anacardic acids. Among these, gallic acid, β -glucogallin, penta-O-galloyl- β -D glucose, quercetin

3-O-galactoside, quercetin 3-O-glucoside, and anacardic acids represent the most abundant constituents (Sevcan et al., 2017). Anacardic acids are phenolic lipids, chemical compounds and a mixture of several closely related organic compounds. Each consists of a salicylic acid substituted with an alkyl chain that has 15 or 17 carbon atoms. The alkyl group may be saturated or unsaturated. The non-linear structure, unsaturation in the alkyl chain and substitution to phenolic group open up new vistas in the innumerable applications in dyestuffs, foods, flavors, ion exchange resins, paints, plasticizers and polymers (Syed et al., 2020). Figure 1 is an image of anacardic acid.

Figure 2. Anacardic acid. The R is the side chain which is variable and contains different number of double bonds (saturated or unsaturated). Obtained from https://www.wikiwand.com/en/Anacardic_acids on February 13, 2022.

“Anacardic acid is a hydroxybenzoic acid that is salicylic acid substituted by a side group at position 6. It is a major component of cashew nut shell liquid and exhibits an extensive range of bioactivities (Figures 2 and 3). It has a role as an EC 2.3.1.48 (histone acetyltransferase) inhibitor, an apoptosis inducer, a neuroprotective agent, an EC 3.4.22.69 (SARS coronavirus main proteinase) inhibitor, an anticoronaviral agent, an antibacterial agent, an anti-inflammatory agent and a plant metabolite. It is a hydroxybenzoic acid and a hydroxy monocarboxylic acid. It derives from a salicylic acid (National Center for Biotechnology Information, 2022).” It is a yellow liquid partially miscible in alcohol and ether but nearly immiscible in water (Kumar et al., 2002). Cardanol and cardol are some derivatives of Anacardic acid; they are phenolic components and less effective in biological activity. Figure 4 is anacardic acid and its derivatives. This work focused on the extraction of anacardic acid from pistachio hulls using three solvents: hexane, ethyl

acetate and mixture of H₂O/MeOH/HCl in order to know the efficient solvent.

MATERIALS AND METHODS

Sample extraction procedure

The pistachio hull was grinded and homogenized. The sample was divided into six aliquots and the mass weighed by balance and recorded in Table 1. Three solvents were used for the extraction procedure namely: hexane, MeOH/H₂O/HCl, and ethyl acetate. The solvents were chosen considering the polarity of the Anacardic acids. The greater the length of the side chain of the Anacardic acids, the less polar. The three solvents were used to obtain the more efficient extraction solvent. Anacardic acids are less soluble in more polar solvent. The hexane was used for extracting aliquots 1 and 2. MeOH/H₂O/HCl was used for the extracting of aliquots 5 and 6 and ethyl acetate mixture was used for extracting aliquots 3 and 4 with each composition having a volume of 50ml, and a sample to solvent ratio of 1:10. An ultrasound-assisted extraction, both in bath and probe was used for the extraction in order to compare the effectiveness of the two methods. Ultrasound bath was used for extracting aliquots 1, 2 and 5 and 6. The probe was used for extracting aliquots 3 and 4. The extraction time allowed for each aliquot was 5 min. Using ultrasound probe, sound waves produced by the probe create bubbles around the sample matrix and eventually burst and release temperature and pressure to the surface. This destroys the matrix surface and the analytes are dissolved in the extraction solvent as they encounter it. After the extraction step, the mixture was filtered to obtain the extract which was then concentrated, and optimized for analysis by HPLC, although this was not performed at the laboratory.

Identification of anacardic acids (HPLC-MS and HPLC-DAD)

The analytes identification was done using both HPLC-MS and HPLC-DAD. Although this was not performed at the laboratory, a standard compound of the anacardic acids was purchased, and after injecting it into the HPLC system, the retention times, UV absorption spectra, and mass spectra were recorded. After the HPLC analysis of the unknown anacardic acids, the retention times, UV spectra, and mass spectra were compared to the standard to identify the unknown anacardic acids. In this experiment, the results of the unknown anacardic acids were compared to the results in the literature for qualitative and quantitative analysis. Considering the HPLC-DAD, the diode array detector gave a UV/vis spectra and chromatogram. The UV/vis spectra has an absorption at around 310 nm which is typical for anacardic acids as recorded in the literature and observed from the spectra in Figure 3. The HPLC chromatogram gave peaks in retention time range of 50 to 60 min which is similar to the range recorded in the literature and helped in the identification purposes. These chromatogram peaks correspond to monoene, diene, and triene anacardic acids; the main peaks of anacardic acids. Considering the HPLC-MS, the mass spectra m/z values of the unknown anacardic acids were compared to m/z values of the anacardic acids in the literature which also helped in the identification of the unknown anacardic acids.

Quantification of anacardic acids (HPLC-DAD)

For quantification purpose, although not performed at the laboratory, stock solution of the anacardic standards can be prepared and diluted to different concentrations or each solution

Table 1. Mass of aliquot, and extraction solvent used in the extraction procedure.

Aliquot	Mass weighed (g)	Extraction solvent (ml)
1	0.5046	Hexane
2	0.5009	Hexane
3	0.5055	Ethyl acetate
4	0.5033	Ethyl acetate
5	0.5041	H ₂ O + MeOH + HCl
6	0.5002	H ₂ O + MeOH + HCl

Source: Author

with different concentration can be prepared separately. The alkyl chain of the anacardic acids do not affect the wavelength to a greater extent; therefore only one anacardic acid standard can be used for all the anacardic acids present in the pistachio hull. The different concentrations can be prepared for a maximum of about 6 experiments. The standard is injected into the HPLC-DAD system and the absorbance recorded for each concentration injected. A calibration curve is prepared by plotting the absorbance of each of the spectra curves for the maximum experiments versus the different concentrations. Hence, from the absorbance of the

unknown anacardic acids, and by plotting on the standard calibration curve, the concentration of the unknown anacardic acids can be found.

RESULTS AND DISCUSSION

The solvents used in the extraction were hexane; ethyl acetate; and MeOH/H₂O/HCl. MeOH/H₂O/HCl gave the

Figure 4. Anacardic acid and its derivatives. Figure obtained from Hemshekhar et al (2012). Emerging Roles of Anacardic Acid and Its Derivatives: A Pharmacological Overview. Basic & Clinical Pharmacology & Toxicology 110: 122-132. <https://doi.org/10.1111/j.1742-7843.2011.00833.x> on February 13, 2022.

Figure 5. DAD spectrum of Anacardic acids. Absorbance recorded at around 310nm. This wavelength is similar to all the Anacardic acids since the side chain does not affect their wavelengths to a greater extent.

Source: Author

poorest results as observed from the HPLC chromatogram in Figure 6. The solvents were chosen based on their polarity considering the polarities of the Anacardic acids. The peaks correspond to monoene, diene and triene Anacardic acids with double bond in the alkyl chains of 1, 2 and 3 respectively. Hexane which is mostly non-polar gave the highest peaks for the anacardic acids followed by ethyl acetate. The limited solubility of the anacardic acids in the MeOH/H₂O/HCl mixture led to the poorest results (Sevcán et al., 2017). The polarity of anacardic acid depends on the length of the alkyl group side chain and whether the alkyl group is saturated or unsaturated. Increasing the unsaturation increases the polarity of the anacardic acid-increasing the side chain length decreases polarity. In this work, four saturated anacardic acids were detected with varying side chain length (Table 2). Anacardic acid 11:0 (The ratio attached to the Anacardic acids name correspond to the number of carbon chains in the alkyl group attached to the Salicylic acid (first number) and the number of double bonds present in the alkyl chain (second number)ⁱ has the shortest side chain and 17:0 has the highest side chain. The anacardic acids in increasing polarity are: 17:0, 15:0, 13:0, 11:0, 17:1, 16:1, 15:1, 13:1, 13:2 and 15:3. Anacardic acid 15:3 has the highest degree of unsaturation; the remaining have one or two degree of unsaturation with varying side chain and fairly less polar.

This explains the more efficient extraction with hexane. In the work of Edoga et al. (2006), hexane was used as extraction solvent for extracting polyphenols from cashew nut shell. They obtained 30% Anacardic acid after separation from other polyphenols. Chitra et al. (2020) also used hexane and methanol to extract cashew nut shell liquid from cashew nut. The cashew nut shell liquid contains Anacardic acid and other polyphenols.

Maria et al. (2012) also obtained greater concentration of monounsaturated Anacardic acid using supercritical CO₂ (40°C, 300 bar, 4 h). This supports the argument that, the efficiency of extraction depends on the degree of unsaturation and polarity of the extracting solvent. The penetration of the solvent in the Anacardic acid solute is less efficient and extraction is poor. Considering the two extraction techniques utilized in this work, the ultrasound probe gave a better extraction results compared to the bath. This could be due to the excessive temperature and pressure exerted when the bubble bursts on the sample matrix surface. Ultrasound probe uses sound waves to create bubbles of the extracting solvent which bursts and releases pressure, increasing the penetration in the solute. The HPLC-DAD (Figure 5) gave an absorbance of around 310 nm and HPLC chromatogram (Figure 6) of retention time range of 50-60 min of anacardic acids. This wavelength is similar to all Anacardic acids due to less effect of the side chain in its absorbance-hence only one

Figure 6. DAD chromatogram of Anacardic acids. Hexane with blue colour gave the best extraction results and the poorest is MeOH/H₂O/HCl mixture with green colour. Anacardic acids are soluble in hexane than MeOH/H₂O/HCl mixture. The mixture is more polar than hexane.

Source: Author

Figure 7. Mass spectra of anacardic acids.

Source: Author

Anacardic acid standard was used for quantification. The HPLC-MS (Figure 7) gave the mass spectra of the Anacardic acids as recorded in Table 2. The most abundant m/z ratio is 373.2 which is also reported in the literature as 373; it corresponds to Anacardic acid 17:1 with an absorbance of 312 nm.

Anacardic acid 11:0 gave the lowest m/z ratio of 291 and UV/vis absorption of 308 nm. Anacardic acid 15:0 and 17:1 have very close results with retention time of 92 and 92.2 min and absorbance of 311 and 312 nm, respectively but different m/z values. To improve the analytical method, the column and stationary phase can be changed in order to improve the chromatographic performance. Also, the time for the extraction of the

Anacardic acids using the MeOH/H₂O/HCl mixture must be lowered in order to prevent the extraction of the polar matrixes, thus gallic acid, β -glucogallin, penta-O-galloyl- β -D glucose, quercetin 3-O-galactoside, and quercetin 3-O-glucoside. With HPLC, the diode array detector can measure the entire wavelength range which is an advantage. In a case where the retention time of two analytes is very close, by comparing the UV/vis spectrum and also mass spectra, the analytes can be identified. Also, UHPLC is another alternative which is faster than HPLC and with small column particle sizes could improve the resolution of the peaks. Moreover, a replicate extraction for each solvent could be performed for better results. Maceration method using methanol only as

Table 2. M/z values of Anacardic acids. Anacardic acid 17:1 is the most abundant and 11:0 is the least abundant.

M/z	Compound
291	Anacardic acid 11:0
315	Anacardic acid 13:2
317	Anacardic acid 13:1
319	Anacardic acid 13:0
341	Anacardic acid 15:3
345	Anacardic acid 15:1
347	Anacardic acid 15:0
359	Anacardic acid 16:1
371	Anacardic acid 17:2
373	Anacardic acid 17:1
375	Anacardic acid 17:0

Source: Author

extraction solvent could also be an alternative. In this case, the pistachio hull is broken into smaller pieces and soaked with the methanol in an airtight container (Aliefman et al., 2021).

Conclusion

In this work, the extraction of Anacardic acids was achieved using ultrasound-assisted extraction, both probe and water bath. Ultrasound probe was the most efficient extraction technique compared to bath as sound wave generates bubbles in extraction solvent which burst and increases penetration in the solute to extract the Anacardic acid with greater pressure and temperature. Hexane as extraction solvent gave the highest gas chromatogram peaks of Anacardic acids due to greater solubility of the Anacardic acids. Mixture of methanol, water and hydrochloric acid gave the poorest gas chromatogram peaks as the Anacardic acid is less polar and solubility decreases. Ethyl acetate gave an intermediate result due to less polarity compared to the mixture of solvents. Anacardic acid in pistachio hull has biological benefit to health.

CONFLICT OF INTERESTS

The author has not declared any conflicts of interests.

ACKNOWLEDGEMENT

All chromatograms, mass spectrum and table of results were obtained from Dr. Manuela Cortese-Laboratory technician at University of Camerino.

Full Length Research Paper

Ear and eye training: Algorithms for the advanced student of audio, image, and video engineering

Michail Chourdakis

Department of Music Studies, University of Athens, Greece.

Received 25 September, 2022; Accepted 18 November, 2022

A lot of research has been taking place when it comes to audio, image, and video processing. Whereas the algorithms involved are very sophisticated, there is still an issue when they need to be taught to students, mainly because they are difficult to comprehend and they require an experienced trainer to guide the students. This article presents an analysis of two of our algorithms designed for ear and eye training, for the student that wishes to immerse himself in multimedia engineering.

Key words: C++, ear training, eye training.

INTRODUCTION

There is always a demand for courses related to audio and video, due to the high popularity of social media and present time high-speed internet availability which makes it possible to exchange large amounts of media. For these advanced lessons to be effective, certain conditions should be present: a good student's background in related fields (math, physics, etc.); high-level source of reading material; access to dedicated software and hardware; and adequately proficient trainer. For the first three conditions above there is already a plethora of possibilities for most budgets. Most students can take courses in basic computer usage; also they can find books and computer applications, capable of many basic and advanced audio, image, and video processing. This article is concerned with the *human trainer* in and how they might be replaced by *computer training*. For example, when equalization in an audio mixing process is discussed (Bobby, 2017), most people can understand

the features of a parametric equalizer, but most cannot detect them when they are applied in the sound. When a gaussian blur is to be applied to an image, the effect is instantly visible but when the image is already blurred only a few can detect the parameters used to blur (Gedraite and Hadad, 2011). For the student to adequately understand the mechanisms of the signal processing, a capable trainer must be present. The other fact that stirs our interest is the ability of the student to be trained with his own material (sound sources and images). All existing applications use predefined material known to work in specific situations (for example, for color testing a full-color sea image is the testing material). The idea of our algorithms is to pick from the list of the files that the student will feed them, the best material for each of the training exercise. This describes the research to automate the student's training via a combination of computer algorithms, developed for Windows in C++ and

HLSL. C++ is the most advanced programming language and the templates feature (Vandevorde et al., 2017) is particularly useful in our development to aid progress in various-precision models. Windows is the de facto standard for multimedia developing due to the emerging and easy-to-use audio and video libraries, namely, Direct3D and Direct2D (Luna, 2012) for hardware accelerated drawing and ASIO for low-latency audio input/output. HLSL is a C-like language capable of directly addressing the Graphics Processing Unit (Halladay, 2019) which allows us to create fast applications that process images directly into modern graphics cards. (Table 1.) We applied the algorithms discussed in our school advanced image and video classes and we presented statistics with the results of our students' training status, and we licensed our applications to be used from teachers and students in our school.

METHOD

The study applied to a population of 150 high school students in Music School of Alimos in advanced music and image processing classes in 2018 to 2019, 2019 to 2020, 2020 to 2021 and 2021 to 2022. All these students are between 16 and 18 years old, attending the last levels of a normal high school curriculum in music schools. The majority (about 75%) are male students and the vast majority (90%) are about to attend science/engineering-related courses in the university.

This curriculum includes optional courses about advanced sound and multimedia processing. They are separated into three groups, "beginner" (that is, students that have never used any audio/video/ image processing software, about 75%, "intermediate" (students which have some familiarity with such or similar software, about 20%) and "advanced" students that have a good level of familiarity with such apps, about 5% (Table 2).

All algorithms are applied to all students in separated

classes and the tables cited describe how their success response is recorded for each of the algorithms described. They are given multiple choice questions within our specialized software and their answers are recorded when a course is applied with or without the algorithm.

- In each algorithm, we will describe:
- What the human trainer would do,
- What the algorithm does and how it tries to fix potential human trainer errors,
- What would the current training applications do (if any),
- The results after our algorithms were applied to the students at three levels (beginner, intermediate, advanced),
- What would be needed in further research.

RESULTS AND DISCUSSION

Ear training

General

By saying 'ear training' we do not mean the generic (French: 'Dictée') applications that are taught in conservatories, primary schools, elementary music theory and in various applications online. In contrast, we mean the training of comprehension of the core sound elements (frequency, duration, amplitude) to aid the student work in sound engineering (composing, recording, mixing, and mastering) applications. An ear training application must take the following considerations into account: the room in which the sound will be heard and whether earphones will be used or not; and the nature of the sound used to train. The environment used for hearing is significant but, since almost no students own any expensive equipment, our algorithms were designed with medium-range

Table 3. Shows the results when the algorithm is applied

Variable	Beginner %	Intermediate %	Advanced %
Human trainer	71	75	84
Algorithm trainer	75	78	88

Source: Author

Table 4. Shows the results when the algorithm is applied

Variable	Beginner %	Intermediate %	Advanced %
Human trainer	82	89	94
Algorithm trainer	86	92	98

Source: Author

equipment in mind, such as a decent set of active studio monitors or headphones. The type of sound to used for training is the reason why our algorithms functioned correctly. Our algorithms can detect that and exclude such audio sources when EQ testing is running. On the other hand, it pays to train compression in common scenarios that are known to need it, for example the compression of a drum kit in a pop song.

Equalizer

The equalizer is an audio filter that lowers or raises selected frequency ranges in an audio signal (Senior, 2018). The experienced human trainer would, knowing the three basic goals of equalization (Clearness, Boosting, Fit) (Bobby, 2017) that, to train for equalization, a sound source of at least two instruments with clearly separated (Senior, 2018) predominating frequency ranges is needed. Common human errors (Chourdakis, 2022) in sample picking include: picking single-instrument sources only with a limited range, such as a flute, picking sources that contain similarly predominating frequency ranges (like a violin with a viola) which EQ testing is pointless, and picking sources that contain instruments that would never function well in an equalizer pattern (such as picking a dull-sounding electric piano and then trying to make it bright by raising the 5KHz area – there is nothing to raise but noise there) (Bobby, 2017). Existing EQ training courses such as Sound Gym (Sound Gym, 2022) will present the user with a predefined set of sources, carefully selected for the correct task. Our algorithms will aid the user pick the correct sound sources from their *own* sound collection, so, after the algorithm is fed the source songs, then it performs the following steps:

1. FFT scans (Smith, 2007) the source to ensure that only areas that contain a full range of frequencies are

presented to the user. This way the above errors are avoided because poor frequency range sources are excluded.

2. Scans for beats (Smith, 2007) to include or exclude parts of the song based on the user's selection of the genre (Stark 2007) for example, pop songs containing full drum kit is tested for higher frequency equalizations.

3. Selectively applies our pitch detection algorithms (Chourdakis, 2007) to have an idea on what sort of instruments are contained in the sound source. For example, vocal music is detected from our algorithms and the equalizer then is biased through the frequency picking area (for example, in female singers, frequencies that boost the 'presence' of the voice in the range of 2500 to 3500 Hz are more likely to be selected for the training).
4. Based on the user's selection of frequency difficulty (1 to 5), limits the testing range of the frequencies. The higher the difficulty, the smaller the range is tested.

5. Based on the user's selection of amplification difficulty (1 to 5), options are presented on how much should the boost (or attenuation) be.

Further research on this subject would be to enable the algorithm to decide the filtering algorithms (Chebyshev, Butterworth etc.) Table 3 and 4 to be used depending on the equalization needs (for example, if tests in a low pass filtering require precise cut off, a Chebyshev I filter would be selected) (Hamming, 1997).

Compression

Testing a compressor is more complex because two main parameters are required (Senior, 2018): *threshold* and *ratio*. The inexperienced human trainer would probably: pick sources that they are already compressed, pick sources that do not need that much (if at all) compression, such as plain classic piano, or test high compression ratios where only lower ones have a meaning (such as testing vocal sources). Our algorithm is fed the source

Table 5. Shows the results when the algorithm is applied

Results/students	Beginner %	Intermediate %	Advanced %

songs and performs the following steps:

1. Scans the amplification of the source with the aid of an audio fingerprint (Jang et al., 2009) algorithm to ensure that the areas containing similar instruments have an almost full amplitude range (that is, they are *not* already compressed). Many sounds found on YouTube or those that are generated from electronic instruments are already compressed; these are discarded from the list.
2. Songs containing beats (Smith, 2007) are more aggressively scanned for full amplitude range because, especially in mastered mixes, drumkits are already compressed. Generally, no-beat songs and vocal songs are preferred. Existing solutions provide their own beat recordings which are uncompressed.
3. Depending on the user selected difficult level, presents tests either with only the ratio (with a fixed threshold value), or with only the threshold (with a fixed ratio value) or with both attributes being variable.
4. Songs that contain vocals are mainly tested for *threshold* because ratio is usually low in these compression modes; Songs that contain drums are mainly tested for *ratio* because threshold is usually fixed in these modes.

The compression test is a difficult process for the students. It requires continuous exercising on many music genres and a good pair of monitors. Further research in this algorithm would be to enable the manipulation of the attack and the release parameters in order to train the ear on how fast (or slow) the compressor is applied or erased.

Time variance

It is expected from a mastered audio piece to have some level of rhythm quantization, especially for the beats. However, the student ought to have the capability to detect the *need* for quantization and therefore, to become trained to detect small variances in the rhythm. This time the experienced human trainer will almost always pick the correct sources, because they are already manually trained in detecting rhythm inaccuracies. Our algorithm, therefore, will only pick songs with a continuous beat pattern, helping the student exclude sources without it.

The algorithm will apply the beat detection and will also reject songs that are already quantized (Katz, 2015), while the rest of the songs will be presented to the user with a ratio selection (depending on the difficulty). The ratio varies between 0.5 (half time) and 2.0 (double time). This time the results are finer for our students because time stretching is relative (that is, they compare acoustically the unstretched sound to the stretched sound). A better version of the algorithm would be required to separate the beats from the rest of the sound for the student to focus on the rhythm.

Pitch variance

In contrast with the previous time stretching formula, pitch altering *does* have meaning in vocal songs where the pitch is likely to fault. It is true that in instruments without fingerboards (like the violin) pitch testing also applies, but our algorithms focus only on vocal songs which are far more common recordings between students than strings instruments. The drawback in this training course is that one must pick specific sources; Ready songs found online are not likely to have pitch faults. Therefore, one class of students must be able to produce their own vocal recordings and then another class of students shall be trained to detect pitch faults in them.

Therefore, our algorithm detects the vocal sounds and then intentionally alters the pitch randomly in order to create instability; applies both the generic pitch detection (Chourdakis, 2007) and specific pitch detection algorithms related to special genres. For example, in Byzantine Music the notes are not fully semitones (100 cents) but can be as small as 16 cents (Chourdakis, 2012); Table 5 and 6 presents the user with pitch shift options, depending on the type of music scale used (Semitone based or Byzantine based etc.). Further research in this field would be able to detect pitch faults in existing (preferably bare) vocal sources, something that would need adequate pitch recognition and source separation.

Panning detection

The final application of our ear training algorithm helps

the student to detect audio placement, that is, where the sound comes from. For this, a multiple 5.1 or 7.1 monitor set is also useful if available (3D testing). The human trainer now must manually adjust the pan to the mono or stereo sources that are likely to be available. Our algorithm does this automatically: in monophonic signals the Semiautonomous Audio Panning System (Gonzalez and Reiss, 2010) is applied to separate them to stereo signals; and in multi-channel signals, their amplification is adjusted to simulate surround movement if a 3D testing is needed, or they are converted to stereo if a 2D testing is needed. When doing a 2-D pan testing, the algorithm presents a level to the student (from -1 to 1) asking him to place the sound. This obviously requires headphones or a well-aligned placing of the monitors. When doing 3-D pan testing (Amin, 2017), the user uses our 3D designer to place a floating orb in a virtual room, depending on the placement of the sound. Further research in this algorithm would include the ability to detect how much a stereo recording is already separated and the ability to decide where to expand or shrink the pan. In 3D the ability to use known transformations to manipulate the sound (for example, rotate the entire source by 90 degrees) would allow the student to be trained with multiple-choice questions (instead of manually having to place the floating orb).

Miscellaneous training

There are a lot of other audio algorithms that can be used for training such as reverb detection, modulation detection, noise detection, vibrato detection. We are trying to enhance our algorithms as much as possible to cover an even broader section of audio training.

Eye training

General

Eye training is different from ear training. Table 6 to 9 summarizes the differences. Our algorithms do not consider hardware or compression situations. Unless the image is HDR, or the video is \geq 4K in resolution (an unlikely situation for schools as of 2022) everyone has adequate hardware to view and image or a video in full quality. Related to compression, perfect quality is assumed by our algorithms because video streaming processors such as H.265 and VP90 (Sullivan et al., 2012) heavily interfere with various video features such as colors. Another thing to consider is the actual ability of the computer to train the student. Whereas, in the sound field, the computer could relatively easily pick optimal

Table 9. Shows the results when the algorithm is applied

Variable	Beginner %	Intermediate %	Advanced %
Human trainer	51	54	59
Algorithm trainer	52	57	62

Source: Author

parameters for the student training, this is not necessarily true for the eye training. For example, in the fields of image segmentation (Venetsanopoulos and Plataniotis, 2000) and motion detection (Gedraite and Hadad, 2011) the human eye is far more efficient than any algorithm discovered until now; the same occurs in various other fields of image analysis. Therefore, we have a limited number of tests available, and these tests do not significantly enhance the abilities of our students as much as the audio training.

Colour tests

The student must carefully study the features of RGB and HSL coloring in images. A human trainer here would not be able to pick accurate images for training since the levels of the RGB would not be easily visible for selection, the human eye is more sensitive to luminance changes than to hue changes (that's the basis of the YUV formats). Our algorithm finds the histogram of the images selected by the user and only picks images with a full histogram (that is, images that have a high range of exposure in all colors, both dark and bright). Images in grayscale (or images with low saturation generally) are excluded as well. Then, it performs various color tests: color hue rotation (helps the student to detect the hue of the color); saturation rotation (helps the student to detect the intensity of the colour); luminance rotation (helps the student detect the power of the light); and color matching between different images (Venetsanopoulos and Plataniotis, 2000) to allow the student to give a ratio of difference between images. A better version of the algorithm would pick only images with large areas of similar hue values (like a sky) in order to help the student work with the hue rotation only in real-life images.

Filtering

Like audio filtering which is usually an application of the Z-Transform in infinite filters (Hamming, 1997), image and video filtering is usually an application of a 3x3 or 5x5 convolution kernel (Shapiro and Stockman, 2001) that results in image sharpening or image blurring. This time the teacher would pick the correct images for testing because kernel filters like blur or sharpening are easy to detect. What our algorithm will do here is to perform a

sharpening on all images, followed by a focus-unblur algorithm (Yuzhikov.com, 2022) to only select images that are not already defocused or blurred or heavily sharpened. Then questions the user based on the difficulty level on the power level of either a blur, or a sharpening. The test is difficult. Our students have difficulties in detecting the kernel parameters even when the images are picked with the above parameters. A better version of the algorithm would only select images with clearly defined shapes (rectangles, triangles etc.) so blurring would be easier to detect.

Lighting

Apart from color and filtering, there are other various effects to be tested in an image such as: brightness/exposure, opacity, chroma keying and highlights/shadows. Essentially these are applications of the light (Evening, 2018); Brightness/Exposure/Opacity change the light to the entire image, whereas the highlights, shadows and the chroma key change specific portions of the light. The algorithm will, depending on the user selection of difficulty, pick images that have a full range of light or opacity value (that is, 0 to 255) and with both dark and bright elements for the 'hard' level and pick images that have a low range of light (most of the image is bright or dark) for the 'easy' level. Because the human trainer's eye is sensitive to the luminosity of the images, our last algorithm does not enhance much the training process.

Other effects

There are many other effects (Ke et al., 2005) related to image and video processing such as:

1. Rotation, video stabilization and generic 2D and 3D transforms: We will not consider computer-based training in these because the human eye can more easily detect e.g., an image rotation than the computer.
2. Advanced coloring effects: color temperature, image vibrance, chromatic aberration. These are essentially combinations of color and lightning. We will consider them in the future.
3. Advanced filtering like bilateral and high pass. We may consider them in the future; they are difficult for our students to understand.

4. Distortion effects like shake, zoom, fisheye and warp: The human eye can more easily detect them than the computer.

As new processing algorithms become available, efficient, and reasonably successful, we will consider them to enhance our eye training algorithms.

Conclusion

Our aim is to train our students not only to be able to use the effects discussed here, but to also know when and if they need them, and to which extent. The application of these algorithms in our school in scholar seasons 2020 to 2021 and 2021 to 2022 has aided them to be more efficiently trained especially in sound; In video and image engineering, more work needs to be done, considering Computer Vision (Ke et al., 2005) frameworks such as Open CV and DLib used by our applications. In the future, we hope to be able to expand our training algorithms to fully cover the training needs of audio, image, and video processing.
